Modular Multiplication Without Trial Division

By Peter L. Montgomery

Abstract. Let $N > 1$. We present a method for multiplying two integers (called N -residues) modulo N while avoiding division by N . N -residues are represented in a nonstandard way, so this method is useful only if several computations are done modulo one N . The addition and subtraction algorithms are unchanged.

1. Description. Some algorithms [1], [2], [4], [5] require extensive modular arithmetic. We propose a representation of residue classes so as to speed modular multiplication without affecting the modular addition and subtraction algorithms.

Other recent algorithms for modular arithmetic appear in [3], [6].

Fix $N > 1$. Define an N -residue to be a residue class modulo N . Select a radix R coprime to N (possibly the machine word size or a power thereof) such that $R > N$ and such that computations modulo R are inexpensive to process. Let R^{-1} and N' be integers satisfying $0 < R^{-1} < N$ and $0 < N' < R$ and $RR^{-1} - NN' = 1$.

For $0 \leq i < N$, let i represent the residue class containing $iR^{-1} \bmod N$. This is a complete residue system. The rationale behind this selection is our ability to quickly compute $TR^{-1} \bmod N$ from T if $0 \leq T < RN$, as shown in Algorithm REDC:

```
function REDC( $T$ )
   $m \leftarrow (T \bmod R)N' \bmod R$  [so  $0 \leq m < R$ ]
   $t \leftarrow (T + mN)/R$ 
  if  $t \geq N$  then return  $t - N$  else return  $t$  ■
```

To validate REDC, observe $mN \equiv TN'N \equiv -T \bmod R$, so t is an integer. Also, $tR \equiv T \bmod N$ so $t \equiv TR^{-1} \bmod N$. Thirdly, $0 \leq T + mN < RN + RN$, so $0 \leq t < 2N$.

If R and N are large, then $T + mN$ may exceed the largest double-precision value. One can circumvent this by adjusting m so $-R < m \leq 0$.

Given two numbers x and y between 0 and $N - 1$ inclusive, let $z = \text{REDC}(xy)$. Then $z \equiv (xy)R^{-1} \bmod N$, so $(xR^{-1})(yR^{-1}) \equiv zR^{-1} \bmod N$. Also, $0 \leq z < N$, so z is the product of x and y in this representation.

Other algorithms for operating on N -residues in this representation can be derived from the algorithms normally used. The addition algorithm is unchanged, since $xR^{-1} + yR^{-1} \equiv zR^{-1} \bmod N$ if and only if $x + y \equiv z \bmod N$. Also unchanged are

the algorithms for subtraction, negation, equality/inequality test, multiplication by an integer, and greatest common divisor with N .

To convert an integer x to an N -residue, compute $xR \bmod N$. Equivalently, compute $\text{REDC}((x \bmod N)(R^2 \bmod N))$. Constants and inputs should be converted once, at the start of an algorithm. To convert an N -residue to an integer, pad it with leading zeros and apply Algorithm REDC (thereby multiplying it by $R^{-1} \bmod N$).

To invert an N -residue, observe $(xR^{-1})^{-1} \equiv zR^{-1} \bmod N$ if and only if $z \equiv R^2x^{-1} \bmod N$. For modular division, observe $(xR^{-1})(yR^{-1})^{-1} \equiv zR^{-1} \bmod N$ if and only if $z \equiv x(\text{REDC}(y))^{-1} \bmod N$.

The Jacobi symbol algorithm needs an extra negation if $(R/N) = -1$, since $(xR^{-1}/N) = (x/N)(R/N)$.

Let $M|N$. A change of modulus from N (using $R = R(N)$) to M (using $R = R(M)$) proceeds normally if $R(M) = R(N)$. If $R(M) \neq R(N)$, multiply each N -residue by $(R(N)/R(M))^{-1} \bmod M$ during the conversion.

2. Multiprecision Case. If N and R are multiprecision, then the computations of m and mN within REDC involve multiprecision arithmetic. Let b be the base used for multiprecision arithmetic, and assume $R = b^n$, where $n > 0$. Let $T = (T_{2n-1} T_{2n-2} \cdots T_0)_b$ satisfy $0 \leq T < RN$. We can compute $TR^{-1} \bmod N$ with n single-precision multiplications modulo R , n multiplications of single-precision integers by N , and some additions:

```

 $c \leftarrow 0$ 
for  $i := 0$  step 1 to  $n - 1$  do
   $(dT_{i+n-1} \cdots T_i)_b \leftarrow (0T_{i+n-1} \cdots T_i)_b + N * (T_i N' \bmod R)$ 
   $(cT_{i+n})_b \leftarrow c + d + T_{i+n}$ 
  [ $T$  is a multiple of  $b^{i+1}$ ]
  [ $T + cb^{i+n+1}$  is congruent mod  $N$  to the original  $T$ ]
  [ $0 \leq T < (R + b^i)N$ ]
end for
if  $(cT_{2n-1} \cdots T_n)_b \geq N$  then
  return  $(cT_{2n-1} \cdots T_n)_b - N$ 
else
  return  $(T_{2n-1} \cdots T_n)_b$ 
end if
```

Here variable c represents a delayed carry—it will always be 0 or 1.

3. Hardware Implementation. This algorithm is suitable for hardware or software. A hardware implementation can use a variation of these ideas to overlap the multiplication and reduction phases. Suppose $R = 2^n$ and N is odd. Let $x = (x_{n-1} x_{n-2} \cdots x_0)_2$, where each x_i is 0 or 1. Let $0 \leq y < N$. To compute $xyR^{-1} \bmod N$, set $S_0 = 0$ and S_{i+1} to $(S_i + x_i y)/2$ or $(S_i + x_i y + N)/2$, whichever is an integer, for $i = 0, 1, 2, \dots, n - 1$. By induction, $2S_i \equiv (x_{i-1} \cdots x_0)y \bmod N$ and $0 \leq S_i < N + y < 2N$. Therefore $xyR^{-1} \bmod N$ is either S_n or $S_n - N$.
